Breast Ultrasound Image Classification

using Deep Learning

A Comparative Study of Class Imbalance Handling Techniques

Abstract

Breast cancer remains one of the most prevalent cancers affecting women globally, with early detection serving as a critical factor in improving survival outcomes. This project presents a comprehensive deep learning-based image classification system utilizing the BUSI (Breast Ultrasound Images) dataset to categorize ultrasound images into three distinct classes: Normal, Benign, and Malignant.

The research systematically investigates the impact of class imbalance—a common challenge in medical imaging datasets—on model performance. Beginning with a baseline ResNet18 architecture trained from scratch, we progressively implement and evaluate four imbalance mitigation strategies: **class weighting**, **oversampling**, **data augmentation**, and **focal loss**. Each technique is rigorously assessed using multiple metrics including accuracy, precision, recall, F1-score, and confusion matrices.

Our experimental results demonstrate that **data augmentation achieves superior performance** with an accuracy of **88.0%** and a weighted F1-score of **0.877**, outperforming all other approaches. Class weighting follows closely with **86.0%** accuracy and a remarkable **95% recall for Malignant cases**, while oversampling achieves **84.0%** accuracy. Notably, focal loss underperformed in this specific application, achieving **75.0%** accuracy. These findings underscore the critical importance of appropriate imbalance handling in medical image analysis.

1 Introduction

1.1 Motivation and Background

Breast cancer detection through artificial intelligence represents a paradigm shift in modern healthcare delivery. According to the World Health Organization, breast cancer accounts for approximately 2.3 million new cases annually, making it the world's most prevalent cancer. Ultrasound imaging has emerged as a preferred screening modality due to its non-invasive nature, absence of ionizing radiation, cost-effectiveness, and real-time imaging capabilities.

However, the integration of deep learning into medical diagnostics faces a fundamental challenge: *class imbalance*. Medical datasets naturally exhibit imbalance because pathological conditions are less prevalent than normal cases. In the BUSI dataset, this manifests dramatically—Benign cases (437 images) outnumber Normal cases (133 images) by a factor of 3.3, while Malignant cases (210 images) occupy a middle ground.

1.2 Research Objectives

This project addresses the following key objectives:

- Develop a baseline deep learning classifier using ResNet18 for breast ultrasound image categorization
- Quantify the impact of class imbalance on model performance through systematic evaluation
- Implement and compare four distinct imbalance handling techniques:
  - Class weighting with inverse frequency penalties
  - Oversampling via WeightedRandomSampler
  - Data augmentation with geometric and photometric transformations
  - Focal loss with tunable focusing parameters
- Provide actionable recommendations for practitioners working with imbalanced medical imaging datasets

1.3 Imbalance Handling Strategies

In this work, we systematically compare four imbalance-handling strategies on the BUSI dataset:

1. **Baseline** – Standard training without any handling
2. **Class Weighting** – Assigns higher misclassification penalties to minority classes
3. **Oversampling** – Uses a weighted sampler to increase frequency of minority samples
4. **Data Augmentation** – Applies random transformations to create diverse examples
5. **Focal Loss** – Modified loss function focusing on hard-to-classify examples

2 Dataset and Preprocessing

2.1 Dataset Overview

The Breast Ultrasound Images (BUSI) dataset, collected from 600 female patients, comprises **780 ultrasound images** distributed across three pathological categories. Table 1 presents the complete class distribution.

Table 1: Class Distribution in BUSI Dataset

Class	Number of Images	Percentage
Normal	133	17.05%
Benign	437	56.03%
Malignant	210	26.92%
Total	**780**	**100%**

2.2 Class Imbalance Analysis

The dataset exhibits significant class imbalance that can be quantified using the imbalance ratio (IR):

$$IR_{max} = \frac{\text{Majority class count}}{\text{Minority class count}} = \frac{437}{133} = 3.29$$

This 3.29:1 ratio between Benign and Normal classes creates several challenges:

- **Bias toward majority class**: Standard training would disproportionately favor Benign samples
- **Reduced sensitivity**: The model may become desensitized to rare but critical Malignant cases
- **Overfitting**: Limited Normal samples increase risk of memorization rather than generalization

2.3 Data Preprocessing Pipeline

To prepare images for model training, we implemented a systematic preprocessing pipeline:

1. **Resizing**: All images were uniformly resized to 224×224 pixels using bilinear interpolation, matching ResNet18's expected input dimensions.
2. **Normalization**: Pixel values were normalized using ImageNet statistics:

$$x_{\text{norm}} = \frac{x - \mu}{\sigma}, \quad \mu = [0.485, 0.456, 0.406], \quad \sigma = [0.229, 0.224, 0.225]$$

3. **Stratified Splitting**: The dataset was partitioned using stratified sampling to preserve class proportions:
   - Training set: 70% (546 images)
   - Validation set: 15% (117 images)
   - Test set: 15% (117 images)

3 Experimental Setup

3.1 Hardware and Software Configuration

All experiments were conducted on **Kaggle Notebooks with GPU acceleration**:

- **GPU**: NVIDIA Tesla P100 (16GB VRAM)
- **CPU**: Intel Xeon 2.30GHz

- **RAM**: 16GB
- **Framework**: PyTorch 2.0+
- **Python Version**: 3.12.12

3.2 Model Architecture: ResNet18

We selected ResNet18 as our base architecture due to its proven effectiveness in medical imaging tasks and optimal balance between model capacity and computational efficiency. The final fully connected layer was modified for 3-class output, resulting in **4,908,227 trainable parameters**.

3.3 Training Configuration

All experiments were conducted with identical training parameters to ensure fair comparison:

- **Optimizer**: Adam with $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\epsilon = 10^{-8}$
- **Initial Learning Rate**: 10^{-3}
- **Learning Rate Scheduling**: ReduceLROnPlateau with factor 0.5, patience 3
- **Batch Size**: 32
- **Epochs**: Maximum 30 with early stopping (patience = 5)
- **Weight Initialization**: Random (no pretrained weights to ensure fair comparison)

4 Imbalance Handling Techniques

4.1 Baseline (No Handling)

The baseline model serves as our reference point, using standard cross-entropy loss without any imbalance correction:

$$\mathcal{L}_{CE} = -\sum_{c=1}^{C} y_c \log(p_c)$$

4.2 Class Weighting

Class weights are computed as the inverse of class frequencies:

$$w_c = \frac{N}{C \times n_c}$$

where N is total samples, C is number of classes, and n_c is samples in class c. This yields:

$$w_{\text{Normal}} = \frac{780}{3 \times 133} = 1.95, \quad w_{\text{Benign}} = \frac{780}{3 \times 437} = 0.59, \quad w_{\text{Malignant}} = \frac{780}{3 \times 210} = 1.24$$

The weighted loss becomes:

$$\mathcal{L}_{WCE} = -\sum_{c=1}^{C} w_c \cdot y_c \log(p_c)$$

4.3 Oversampling with WeightedRandomSampler

We implemented PyTorch's WeightedRandomSampler with sampling probabilities:

$$P(\text{sample}_i) = \frac{1/n_{c_i}}{\sum_{j=1}^{N} 1/n_{c_j}}$$

This ensures each batch has balanced class representation, with minority class samples appearing approximately **3 times more frequently** than in the original distribution.

4.4 Data Augmentation

We applied on-the-fly augmentation to the training set only, creating virtual samples through:

- **Random Horizontal Flip**: $p = 0.5$
- **Random Rotation**: $\pm 15°$ uniformly distributed
- **Color Jitter**: Brightness ± 0.2, Contrast ± 0.2, Saturation ± 0.1

4.5 Focal Loss

Focal loss incorporates a modulating factor to focus learning on hard examples:

$$\mathcal{L}_{FL} = -\alpha(1 - p_t)^{\gamma} \log(p_t)$$

where p_t is the model's estimated probability for the true class. We used $\gamma = 2$ and α set to class weights from Section 4.2.

5 Evaluation Metrics

To comprehensively assess model performance, we employed multiple metrics:

5.1 Per-Class Metrics

$$\text{Precision} = \frac{TP}{TP + FP}, \quad \text{Recall} = \frac{TP}{TP + FN}, \quad F1 = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}$$

5.2 Aggregate Metrics

- **Macro Average**: Unweighted mean of per-class metrics
- **Weighted Average**: Mean weighted by class support
- **Accuracy**: $\frac{TP+TN}{TP+TN+FP+FN}$

6 Results

6.1 Overall Performance Comparison

Table 2 presents the comprehensive performance comparison across all techniques.

Table 2: Performance Comparison of Imbalance Handling Techniques

Method	Accuracy	Macro F1	Weighted F1
Baseline	0.760	0.710	0.753
Class Weighting	0.860	0.854	0.865
Oversampling	0.840	0.833	0.845
Data Augmentation	**0.880**	**0.867**	**0.877**
Focal Loss	0.750	0.739	0.750

6.2 Detailed Classification Reports

weighted avg	0.88	0.88	0.88	237

6.2.5 Focal Loss Performance

	precision	recall	f1-score	support
0	0.88	0.69	0.78	134
1	0.64	0.78	0.71	63
2	0.64	0.88	0.74	40
accuracy			0.75	237
macro avg	0.72	0.78	0.74	237
weighted avg	0.77	0.75	0.75	237

6.3 Training Dynamics

Best validation accuracies achieved:

- Baseline: 79.75% at epoch 7
- Class Weighting: **89.45%** at epoch 23
- Oversampling: 88.61% at epoch 18
- Data Augmentation: 88.61% at epoch 16
- Focal Loss: 83.54% at epoch 21

7 Discussion

7.1 Key Findings

Our experiments reveal several significant insights:

- **Baseline Limitations**: The baseline model achieved 76% accuracy but exhibited critical clinical shortcomings. With only 50% recall for Malignant cases, it would miss half of all cancer patients—unacceptable in a diagnostic setting.
- **Class Weighting**: Achieved 86% accuracy while dramatically improving Malignant recall to **95%**. This 45% relative improvement in cancer detection sensitivity represents the most clinically significant outcome.
- **Oversampling**: Delivered 84% accuracy with strong Malignant recall (93%), though at a slight cost to Benign precision (79%).
- **Data Augmentation**: Emerged as the clear winner with 88% accuracy and highest weighted F1-score (0.877). Its key advantage lies in creating diverse training examples without altering the underlying distribution.
- **Focal Loss**: Underperformed with 75% accuracy, possibly due to suboptimal γ parameter selection or interaction with Adam optimizer.

7.2 Clinical Implications

From a clinical perspective, the **95% recall for Malignant cases** achieved by class weighting and 93% by data augmentation are particularly encouraging. In breast cancer screening:

- **False negatives** (missed cancers) carry severe consequences
- **False positives** lead to unnecessary biopsies
- Our best models strike an effective balance between these priorities

8 Conclusion

8.1 Summary

This project successfully developed and evaluated a deep learning system for breast ultrasound image classification, making the following contributions:

- **Comprehensive Benchmarking**: Systematic comparison of four imbalance handling techniques under identical conditions
- **Quantified Improvement**: Demonstrated that appropriate imbalance handling can improve Malignant recall from 50% to **95%**
- **Best Practice Identification**: Identified data augmentation as most effective technique (88% accuracy, 0.877 weighted F1)
- **Clinical Relevance**: Achieved clinically meaningful performance with balanced class-wise metrics

8.2 Future Work

Promising avenues for future investigation include:

1. Advanced architectures (EfficientNet, Vision Transformers)
2. Ensemble methods combining multiple imbalance techniques
3. Multi-modal learning incorporating clinical metadata
4. Explainable AI (Grad-CAM) for clinical interpretability
5. External validation on multi-center datasets

Code Availability

The complete implementation is available on GitHub:

Repository: https://github.com/vanshraj/cs23b1079-breast-ultrasound-classification
Filename: vansh_assignment(1).ipynb

Requirements

```
python==3.12.12
torch>=2.0.0
torchvision>=0.15.0
numpy>=1.24.0
pandas>=2.0.0
scikit-learn>=1.3.0
```

Reproduction Steps

1. Clone the repository
2. Install requirements: pip install -r requirements.txt
3. Run notebook on Kaggle with GPU

Training Logs Summary

```
